Summary of Agricultural Land Classification

and

Soil Resources

November 2017

Reading Agricultural Consultants Ltd
Beechwood Court, Long Toll, Woodcote, RG8 0RR
www.readingagricultural.co.uk

1. Introduction

- 1.1.1. Reading Agricultural Consultants Ltd (RAC) is instructed by Ashfield Land Management Ltd and Gazeley GLP Northampton s.a.r.l. to assess the Agricultural Land Classification (ALC) and soil resources of the proposed Rail Central site at Milton Malsor, Northamptonshire. The main site and land at Junction 15a include 274ha of agricultural land, most of which is in arable use.
- 1.1.2. The Rail Central ES Scoping Report, issued in December 2015, identified that previous ALC surveys had been undertaken by ADAS on behalf of the Ministry of Agriculture, Fisheries and Food (MAFF), that RAC had carried out a reconnaissance ALC survey across most of the site, and that consultation will be required with Natural England to determine whether the existing ALC data provides a sufficiently robust description of the baseline conditions or whether additional ALC surveys would be required.
- 1.1.3. The Scoping Opinion issued in January 2016 included Natural England's view that a detailed soil and ALC survey will be required, with the density of sampling to be one observation per hectare across the site.
- 1.1.4. The Secretary of State noted at paragraph 3.36 of the Scoping Opinion that:

"The existing baseline should be informed by a comprehensive and up-to-date data set and therefore welcomes the proposal to undertake new surveys as well as discussing the suitability of existing surveys with Natural England."

- 1.1.5. This report sets out a summary of the data used to provide the baseline conditions on agricultural land quality and soils reported in the ES. It is anticipated that the dataset can be agreed with Natural England to be a suitable and accurate representation of the ALC and soil conditions across the site.

2. ALC and Soil Survey Data

2.1. ADAS ALC (Annex 1)

- 2.1.1. Just under 66ha of agricultural land in the west of the site was surveyed by ADAS on behalf of MAFF in January 1997¹. The survey was undertaken at a detailed level, including a total of 59 borings and three soil pits.
- 2.1.2. This survey classified the west of the Rail Central site as mostly (37.2ha) Subgrade 3b, with a large proportion of Subgrade 3a (15.2ha) and a small area of Grade 2 (3.4ha).
- 2.1.3. The soil logs are not available, however the report does contain descriptions of each soil type and land grade identified.

¹ **MAFF (1997)** *Public Transport Interchange, Blisworth, Northamptonshire. Agricultural Land Classification, Reference EL 29/02325*

2.2. RAC Reconnaissance Survey (Annex 2)

- 2.2.1. A reconnaissance ALC survey was undertaken across 194ha of agricultural land at the main site in October 1999. A total of 57 soil cores were observed with an auger and three representative inspection pits were dug.
- 2.2.2. The survey classified most of the agricultural land (142ha or 73%) as Subgrade 3b, with 33ha (17%) of Subgrade 3a and 19ha (10%) of Grade 2 also present. The report acknowledges the limitations of the scale of survey, though due to broad patterns of soil type suggests that local changes arising from a detailed survey would not likely be substantial.

2.3. RAC Detailed Survey

- 2.3.1. Surveyors from RAC returned to the site in February 2017 to commence a detailed ALC and soil resources survey. A total of 171 soil profiles were observed across the site with augers and three inspection pits were dug. A number of topsoil samples were also sent to a laboratory for the determination of physical and chemical properties.
- 2.3.2. The detailed survey identified three main soil types across the site. As predicted in the reconnaissance report of 1999, the proportions of each grade classification do not differ substantially. Overall, 200ha (75%) of the site is classified as Subgrade 3b, 36ha (14%) as Subgrade 3a and 28ha (11%) as Grade 2. The detailed survey did however identify a small area of excellent quality agricultural land of Grade 1 in the north of the site, amounting to 2ha or <1% of the area.
- 2.3.3. The soil profile summaries derived from the detailed survey are included in Annex 3.
- 2.3.4. The locations of all observations from the three surveys at the site are shown in Figure 1.

2.4. Soil Types

- 2.4.1. Three main soil types are present at the site. The most extensive type comprises heavy clay loam or clay topsoils over clay subsoils. The subsoil is gleyed and slowly permeable and the profiles are of Wetness Class (WC) III or IV, depending on the depth to the slowly permeable layer. This soil type was identified in all three of the surveys undertaken and is limited by wetness and workability to Subgrade 3b.
- 2.4.2. A minor variant of this type occurs in which the topsoil is of medium clay loam. Where profiles are of WC III, the limitation is less severe to Subgrade 3a.
- 2.4.3. The second soil type is similar in characteristic to the first, though becomes slowly permeable at depth or is otherwise permeable throughout. The 2017 survey found profiles to be of WC II or occasionally WC I and limited by workability according to the topsoil textures. Profiles of WC II with medium or heavy loamy topsoils are limited to Grade 2 or Subgrade 3a respectively. Where the topsoil texture is of clay,

the limitation is to Subgrade 3b. These respective grades improve by one where the profiles are of WC I, resulting in rare instances of Grade 1 quality land.

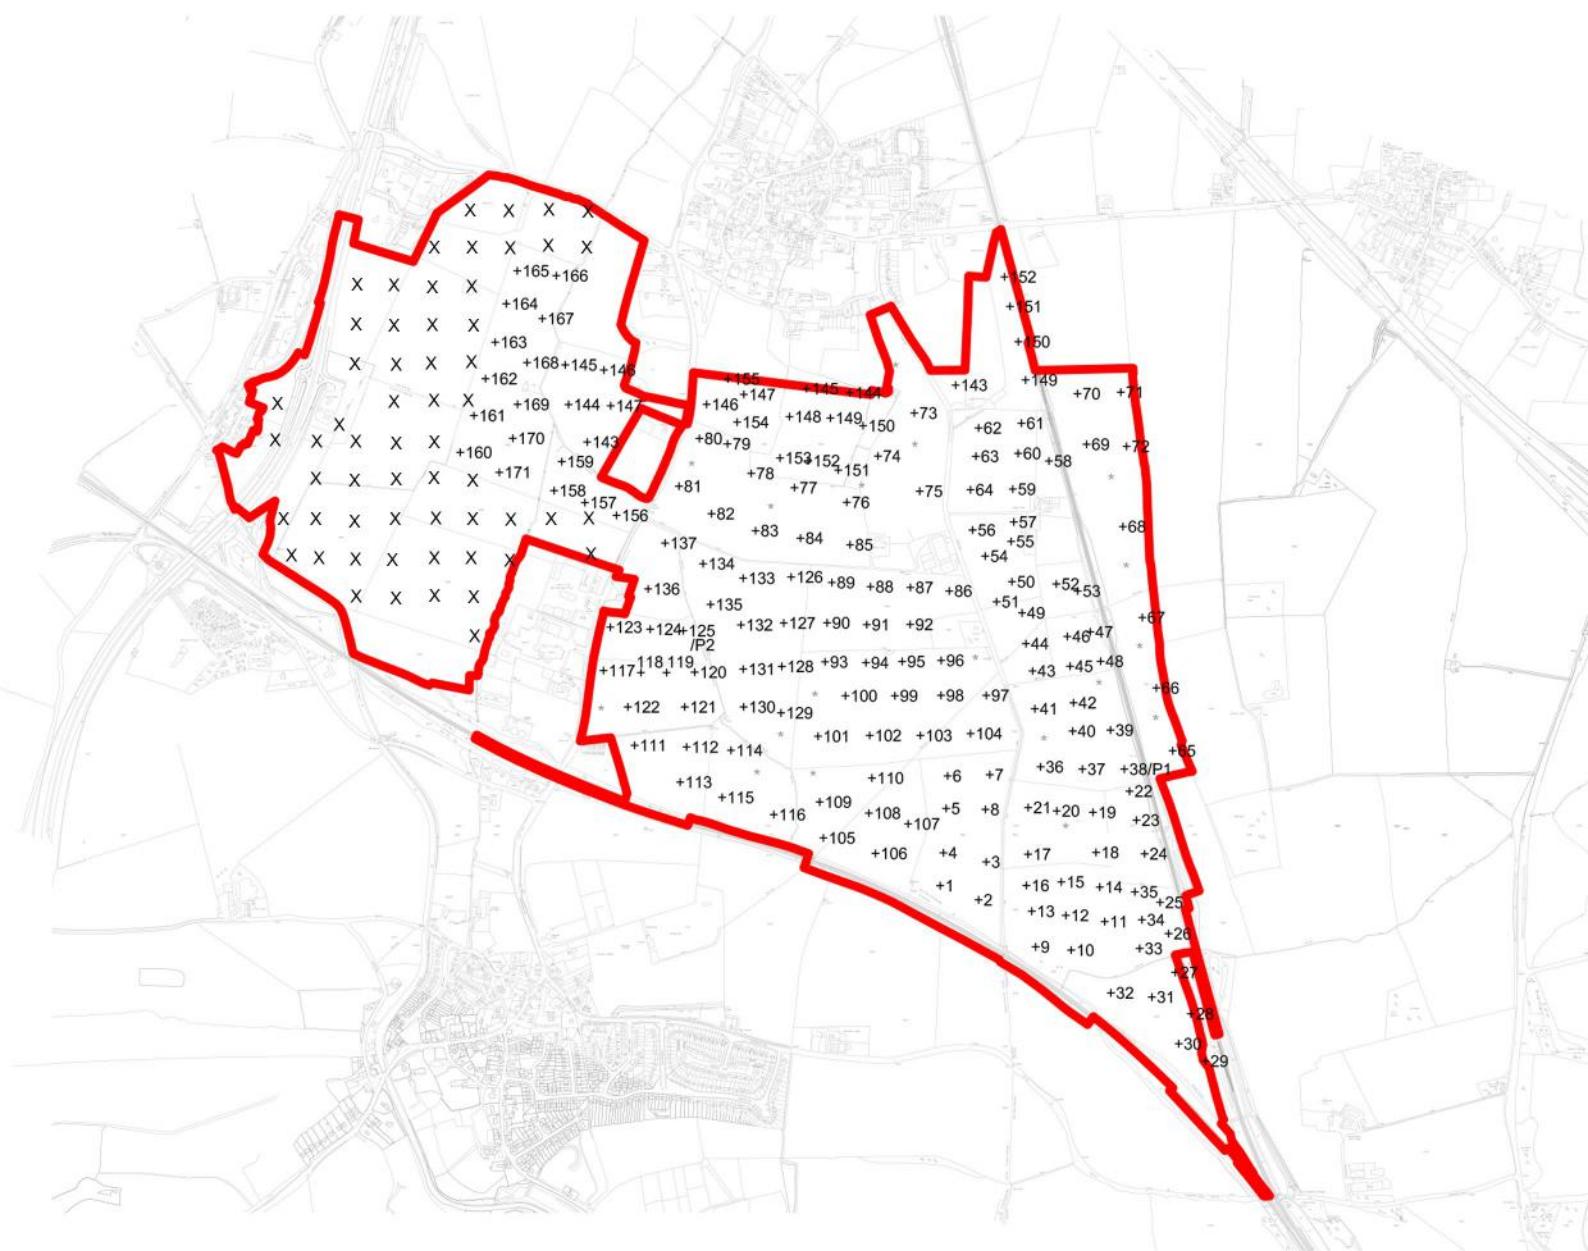

- 2.4.4. The reconnaissance survey of 1999 identified this soil type and classified it mostly as Subgrade 3a. The ADAS survey of 1997 classifies this soil type as mostly Subgrade 3a with some Grade 2.
- 2.4.5. The third soil type is distinct from the first two and comprises coarse loamy textures of sandy loam and sandy clay loam, occasionally with sand at depth. This soil type was identified in the 1999 and 2017 surveys and is classified as Grade 2 or Subgrade 3a, with soil droughtiness representing the main limitation to agricultural land quality.
- 2.4.6. The areas of each ALC grade present at the main site are given in Table 1 and are shown in Figure 2.

Table 1: ALC Areas

Grade	Description	Area (ha)	Area (% of agric. land)
1	Excellent quality	2	<1
2	Very good quality	28	11
3a	Good quality	36	14
3b	Moderate quality	200	75
	Total Agricultural	266	100

3. Summary

- 3.1.1. Cumulatively, a total of 294 observations and nine soil pits have been examined across 266ha of agricultural land at the proposed Rail Central main site. The assessment has therefore been made in accordance with Natural England's Scoping Opinion requiring one observation per hectare.
- 3.1.2. Three main soil types are present. The major soil type comprises poorly drained, clayey profiles of WC III or IV. A second soil type has similar characteristics but is better draining, of WC I or II. Profiles are affected by wetness and workability to varying extents, ranging from Grade 1 to Subgrade 3b.
- 3.1.3. The third, minor, contrasting soil type includes sandy loam and sandy clay loam textures, occasionally over sand. These profiles are of WC I and limited by droughtiness to Grade 2 or Subgrade 3a.

AGRICULTURAL LAND CLASSIFICATION REPORT

PUBLIC TRANSPORT INTERCHANGE BLISWORTH, NORTHAMPTONSHIRE

Introduction

1. This report presents the findings of a detailed, Agricultural Land Classification (ALC) survey of 65.8 ha of land at Blisworth, Northamptonshire. The survey was carried out during January 1997.

2. The survey was commissioned by the Ministry of Agriculture, Fisheries and Food (MAFF) Land Use Planning Unit, Cambridge in connection with an outline planning application for a public transport interchange. This survey supersedes a previous ALC survey on part of this land (ADAS Job No. 3/93).

3. The work was conducted by members of the Resource Planning Team in the Huntingdon Statutory Group in ADAS. The land has been graded in accordance with the published MAFF ALC guidelines and criteria (MAFF, 1988). A description of the ALC grades and subgrades is given in Appendix I.

4. At the time of survey the land use on the site was mainly ploughed land (after maize) with some permanent pasture grassland. A small area in the north of the site appeared to be restored land. Other land includes, some farm buildings, a section of the A43 dual carriageway, a filling station and associated land, a small section of dismantled railway embankment, and in the east a section fenced off for caravan storage. The remainder is associated with the mainline railway and the Grand Union Canal. The area between the railway and the canal is swampy scrubland.

Summary

5. The findings of the survey are shown on the enclosed ALC map. The map has been drawn at a scale of 1:10 000 and is accurate at this scale but any enlargement would be misleading.

6. The area and proportions of the ALC grades and subgrades on the surveyed land are summarised in Table 1.

Table 1: Areas of grades and other land

Grade/Other land	Area (hectares)	% surveyed
2	3.4	5.2
3a	15.2	23.1
3b	37.2	56.5
Other land	10.0	15.2
Total agricultural land	55.8	84.8
Total survey area	65.8	100.0

7. The fieldwork was conducted at an average density of 1 boring per hectare. A total of 59 borings and 3 soil pits were described.

8. Land mapped as grade 2 (very good quality land) occurs in a small area in the north eastern part of the site, and is restricted to this grade due to a slight droughtiness limitation. Land mapped as subgrade 3a (good quality land) occurs in the extreme north western part of the site, and in a narrow ribbon in a north/south direction in the centre of the site. This land is restricted to this grade due to a moderate wetness and workability limitation. The remainder of the land is mapped as subgrade 3b (moderate quality land), and is restricted to this grade due to a more severe wetness and workability limitation.

Factors Influencing ALC Grade

Climate

9. Climate affects the grading of land through the assessment of an overall climatic limitation and also through interactions with soil characteristics.

10. The key climatic variables used for grading this site are given in Table 2 and were obtained from the published 5km grid datasets using the standard interpolation procedures (Met. Office, 1989).

Table 2: Climatic and altitude data

Parameter	Value
Grid reference	SP724550
Altitude (m, AOD)	80
Accumulated Temperature (day °C, Jan.–June)	1396
Average Annual Rainfall (mm)	636
Field Capacity Days	138
Moisture Deficit, Wheat (mm)	106
Moisture Deficit, Potatoes (mm)	98
Overall Climatic Grade	1

11. The climatic criteria are considered first when classifying land as climate can be overriding in the sense that severe limitations will restrict land to low grades irrespective of favourable site or soil conditions.

12. The main parameters used in the assessment of an overall climatic limitation are average annual rainfall (AAR), as a measure of overall wetness, and accumulated temperature (ATO, January to June), as a measure of the relative warmth of a locality.

13. The combination of rainfall and temperature at this site mean there are no overriding climatic conditions, and therefore the climatic grade 1 is assigned.

Site

14. The majority of the site is at a height of approximately 80m AOD rising to 85m AOD on the northern, southern and western boundaries. The site is bounded in the east by open farmland with industrial units in the south east part, in the north by the Milton Malsor Road and industrial units, with open farmland and Station Road in the south. The western boundary largely follows the A43 (T) except where it includes Arm Farm which is on the western side of the main road. There are good examples of 'ridge and furrow' in the fields behind Arm Farm and to a lesser extent in the grass fields in the south of the site. In the arable area the 'ridge and furrow' has been ploughed out leaving a stripey effect of two different colour topsoils in an east/west direction. A small area in the north, adjacent to the industrial units, appears to have been restored.

Geology and soils

15. The published 1:63 360 scale geology map (Geol. Survey, 1969) shows the vast majority of the site to comprise Upper Lias Clay, with deposits of Glacial Sands and Gravel at the northern extreme.

16. The 1:250 000 reconnaissance soil survey map for the area (SSEW, 1983) shows the vast majority of the site to comprise soils of the Denchworth Association which are briefly described as slowly permeable seasonally waterlogged clayey soils with similar fine loamy over clayey soils. In the extreme north, soils of the Wick 1 Association are mapped which are briefly described as deep well drained coarse loamy and sandy soils, locally over gravel.

17. During the current detailed survey three main soil types were encountered.

Soil Type I

18. Soil Type I is confined to a small area in the north east of the site. Profiles typically comprise very slightly stony, slightly calcareous medium clay loam or sandy clay loam topsoil. This overlies slightly stony non-calcareous sandy clay loam or heavy clay loam upper subsoil. Lower subsoil comprises moderately stony, calcareous sandy clay loam (occasionally sandy clay). The soils are free draining and are assessed as Wetness Class I (q.v. Appendix II).

Soil Type II

19. Soil Type II occurs in the north west and in a narrow ribbon in the centre of the site. Profiles typically comprise very slightly stony, non-calcareous medium clay loam (occasionally heavy clay loam) topsoil, over very slightly stony, non-calcareous heavy clay loam upper subsoil. Lower subsoil comprises stoneless non-calcareous clay with gleying occurring at 40/45cm. These soils are typically assessed as Wetness Class III, but occasionally slightly better drained profiles occur (Wetness Class II).

Soil Type III

20. Soil Type III occurs over the remainder of the site. Profiles typically comprise stoneless, non-calcareous heavy clay loam (occasionally medium clay loam) topsoil over

slowly permeable stoneless clay subsoil. Gleying occurs at 30/35cm and the soils are assessed as Wetness Class IV, or less typically Wetness Class III.

Agricultural Land Classification

21. The details of the classification of the site are shown on the attached ALC map and the area statistics of each grade are given in Table 1, page 1.

22. The location of the auger borings and pits is shown on the attached sample location map.

Grade 2

23. Land mapped as grade 2 occurs in the north east of the site and corresponds to the soils described in paragraph 18. The soils are free draining but with slightly/moderately stony subsoils the land is restricted to this grade due to a slight droughtiness limitation.

Subgrade 3a

24. Land mapped as subgrade 3a occurs in the north west and in a narrow ribbon in the centre of the site, and corresponds to the moderately well drained soils (Wetness Class III) described in paragraph 19, and is limited to this subgrade due to a moderate wetness and workability limitation. With the clay loam topsoils and slowly permeable subsoils care and timeliness with cultivations are required to avoid damage to soil structures. A few better drained profiles (Wetness Class II, Grade 2) were encountered, but these are not in discrete mappable areas.

Subgrade 3b

25. Land mapped as subgrade 3b occurs over the remainder of the site and corresponds to the imperfectly drained soils (Wetness Class IV, occasionally Wetness Class III) described in paragraph 20. With clay loam topsoils immediately over slowly permeable clay subsoils a more severe wetness and workability restriction limits the land to this subgrade. Considerable care and timeliness with cultivations will be required to avoid damage to soil structures.

1. SITE AND CLIMATIC CHARACTERISTICS

1.1 General features and land form

The area surveyed lies to the south of Milton Malsor and to the north of Blisworth, and a main railway line.

The total area surveyed extends to about 200ha which is separated into two by the A43; 148ha to the east and 52ha to the west. Most is agricultural land (194ha) in arable cultivation under winter cereals, stubble or recently ploughed. In the east around Lodge Farm and Milton Crossing and in the west on fields adjacent to Blisworth Junction there is grass which had sheep and cattle grazing on it at the time of survey. The remaining "other" land (6ha) comprises farm buildings and their curtilages, houses and gardens, a track and railway line.

The highest ground is in the east and lies at an altitude of about 95m aOD. The land then slopes gently, locally moderately, to the north to lower ground at about 80m aOD.

Surface form is mainly smooth to gently undulating, although locally in the south adjacent to the railway line there are areas of strongly undulating ground.

1.2 Soil parent materials and natural drainage

There are four main soil parent materials across the site.

The most extensive occurs across the southern half of the site where clayey soils are developed in greyish, stoneless drift. Soil profiles typically comprise dark greyish brown, clayey (occasionally fine loamy) upper layers over greyish, predominantly clayey (locally silty clay), gleyed and poorly permeable lower layers.

On the higher ground to the east of the railway, soil profiles are derived from Chalky Boulder Clay which contains many small chalk stones and occasional flints. There is one main soil type. Soil profiles typically comprise dark greyish brown, non-calcareous, slightly stony, heavy loamy or clayey upper layers over greyish brown and calcareous, clayey, gleyed and poorly permeable lower layers containing many chalk stones.

Natural drainage of both these soil types is mainly by lateral subsurface seepage across poorly permeable subsoil layers.

In the west, similar but non-calcareous soil profiles occur which lack gleying features in the upper layers. Natural drainage of these soils is initially by relatively free vertical percolation down through the soil profiles layers then by lateral subsurface seepage across poorly permeable subsoil layers.

In the north, soils are derived from glaciofluvial drift. Soil profiles typically comprise dark brown, slightly stony, coarse loamy upper layers over brown and yellowish brown, slightly stony, coarse loamy and sandy lower layers. Natural drainage is mainly by relatively free vertical percolation down through the soil profile layers.

1.3 Climatic factors

Climatic factors affecting land quality, especially by their interactions with soil factors, are set out below. These have been interpolated from the Meteorological Office's standard 5km grid point data set for two representative locations SP 736545 (east) and SP 724549 (west) at 85 and 80m aOD respectively.

Average annual rainfall (AAR): 640-642mm

Accumulated temperature >0°C (AT0): 1390-1396day°

Field Capacity Days (FCD): 137-140 days

Moisture deficit - winter wheat (MDw): 105-106mm

Moisture deficit - potatoes (MDp): 97-98mm

The local climate is moderately warm and dry. The FCD regime is just below the national average for lowland England (150 days). The "key" crop-adjusted moisture deficits are moderately large.

2. AGRICULTURAL LAND QUALITY AND MAIN SOIL CHARACTERISTICS

2.1 Soil survey methods

Fifty-seven soil profiles were examined at regular intervals using Edelman (Dutch) augers and spades at the approximate locations shown on Plan RAC 1, giving an observation density on the agricultural land of about 1 per 3.5ha. Soil physical characteristics were also examined in more detail in three soil inspection pits (close to the location of selected auger borings): the locations of these are also shown on Plan RAC 1.

Texture; significant stoniness; colours (especially gley mottle colours indicating seasonal wetness), density, degree of fissuring and macroporosity (together indicating structural conditions, permeability and rooting opportunities); free calcium carbonate; organic matter content and thickness were assessed for each main soil horizon to 1.2m depth.

Soil Wetness Class (WC) was inferred from the presence or absence of, and depth to, greyish and ochreous gley mottling and/or poorly permeable subsoil layers at least 150mm thick.

2.2 Agricultural Land Classification (ALC) and main limitations

Soil, site and climatic constraints were evaluated mainly by reference to MAFF's 1988 revised guidelines and criteria.

The most extensive limitation is seasonal wetness affecting the land's workability and accessibility for livestock grazing. The wetness limitation derives from moderately to poorly permeable subsoil impeding drainage to different degrees of severity (depending on the depth of occurrence) and causing seasonal waterlogging of the upper soil profile layers. This constraint limits the land mainly to subgrade 3b, but also subgrade 3a and grade where it is less severe.

Slight droughtiness from reduced soil profile moisture holding capacity is a limitation on land to the north. This limitation constrains land to grade 2.

In the south, on land adjacent to the railway, gradients of between 7 and 11° are limiting to subgrade 3b.

Plan RAC 2 shows the extent and distribution of land in the different ALC grades and subgrades. Most of the agricultural land (about 73%) is lower quality in subgrade 3b (about 142ha). The remaining land is higher quality in subgrade 3a (about 33ha: 17%) and grade 2 (about 19ha: 10%).

These findings are based on a semi-detailed examination. Thus if the land were resurveyed in greater detail it is possible that there would be local changes to the grading. However, it is not anticipated that these would be substantial.

2.3 Brief description of the land subgrade

Grade 2

Land in this grade is the least extensive, occurring mainly in the north.

Soil profiles typically comprise dark brown, very slightly stony, sandy loam (occasionally sandy clay loam) topsoils over brown, slightly stony, sandy loam or sandy clay loam upper subsoils over yellowish brown, slightly to moderately stony, similarly-textured or loamy sand and sand lower subsoils. Occasionally, greyish brown, clayey, gleyed and poorly permeable lower subsoils occur below about 700mm.

These soils are well or moderately well drained (WC 1 or 2) and are constrained by a slight droughtiness or wetness/workability limitation.

Subgrade 3a

Land in this subgrade occurs mainly on land to the west, but also on land to the east.

Soil profiles typically comprise dark greyish brown, very slightly stony, heavy clay loam topsoils over brown or brownish grey, stoneless to very slightly stony, clayey upper subsoils over greyish brown, clayey, gleyed and poorly permeable lower subsoils.

These soils are moderately well drained (WC 2) and constrained by a seasonal wetness/workability limitation.

Subgrade 3b

Land in this subgrade is the most extensive.

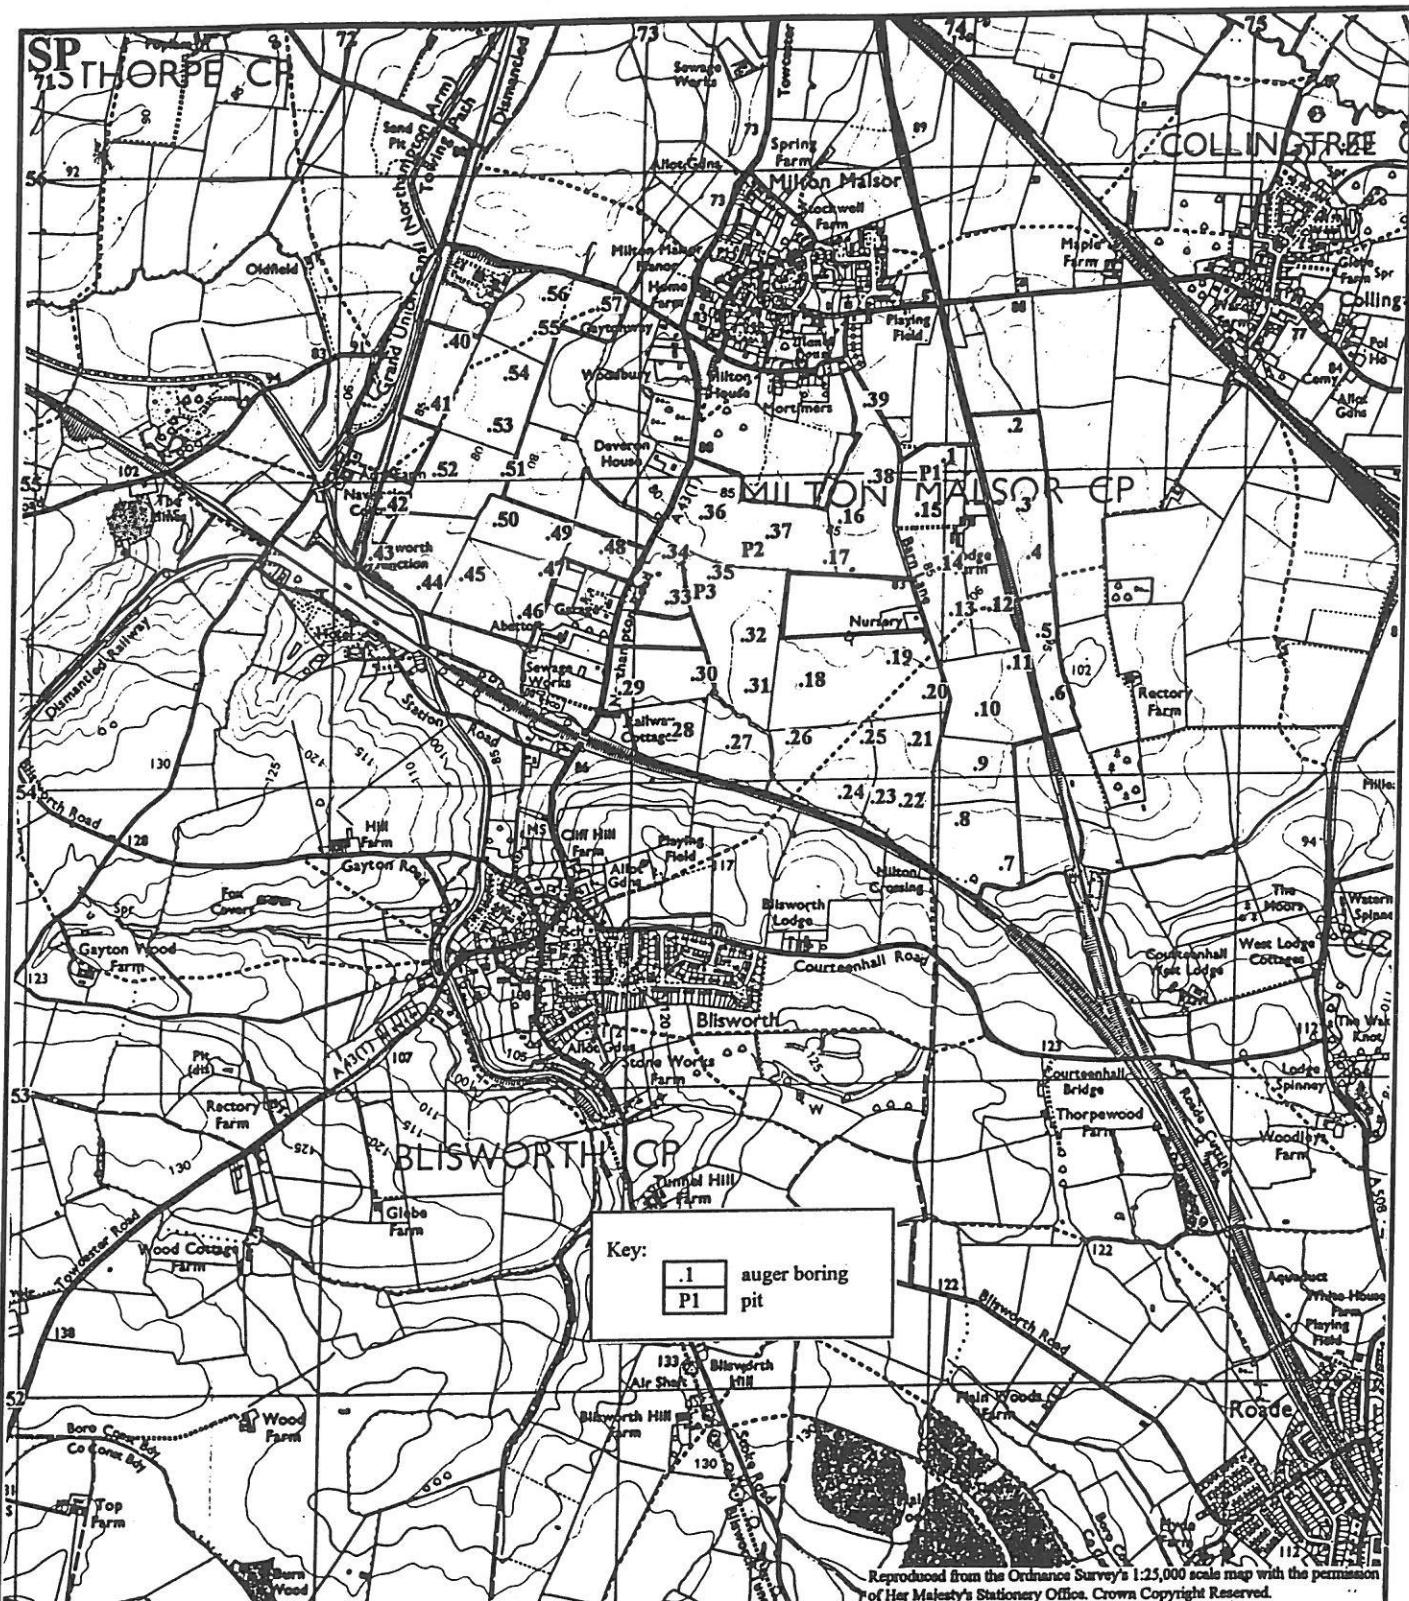

Soil profiles typically comprise dark greyish brown, very slightly stony, clayey (occasionally heavy clay loam) topsoils over greyish brown, predominantly clayey (locally silty clay), gleyed and poorly permeable lower subsoils.

On the higher ground to the east of the railway, soil profiles typically comprise dark greyish brown, non-calcareous, slightly stony, clay or heavy clay loam topsoils over greyish brown, calcareous, slightly stony, clayey, upper subsoils over greyish brown, calcareous, clayey gleyed and poorly permeable lower subsoils containing many chalk stones.

Both these soils types are mainly imperfectly drained (WC 3), occasionally poorly drained (WC 4) and constrained by a moderately severe wetness/workability limitation.

Locally, in the south, on land adjacent to the railway, gradients of between 7 and 11° are limiting to subgrade 3b.
